

Dictionaries

Chris Piech and Mehran Sahami

And Then There Were None

- The term **None** is used in Python to describe "no value"
 - For example, it is the value you would get from a function that doesn't return anything
 - WHAT?!
 - Example:

```
>>> x = print("hi")
>>> print(x)
None
```
 - Comparing anything to **None** (except **None**) is False
- Why does **None** exist?
 - Denotes when the suitcase for a variable has "nothing" in it

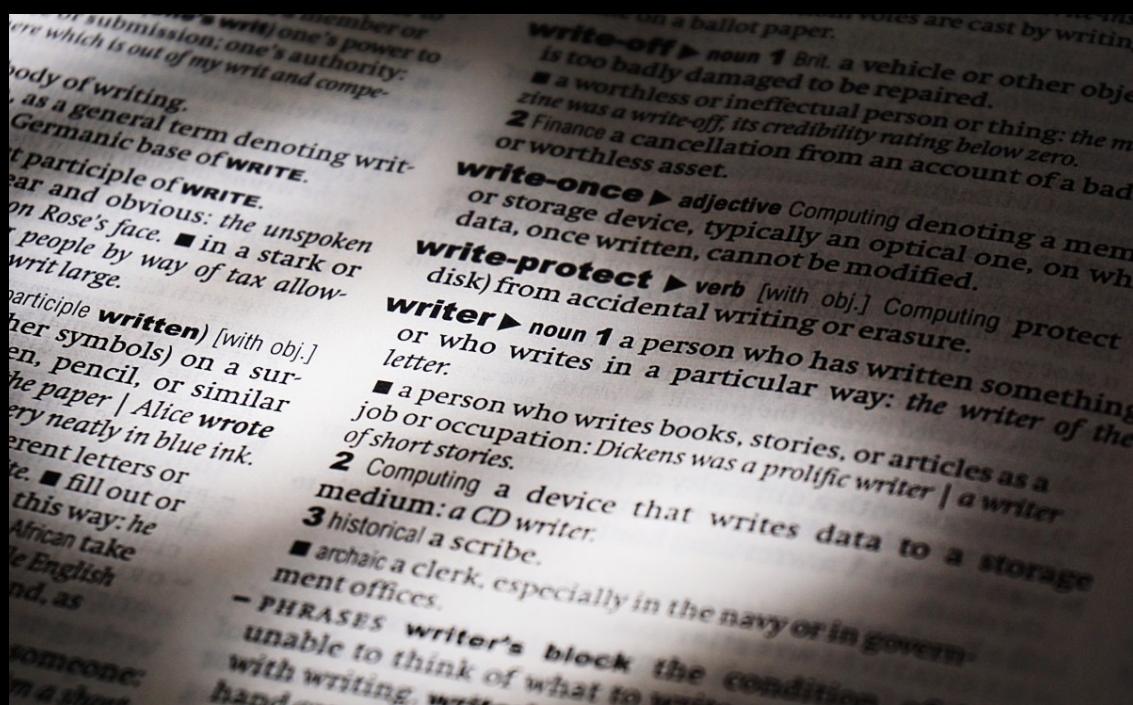

Learning Goals

1. Learning about dictionaries
2. Building programs using dictionaries

Dictionaries

What are Dictionaries?

- Dictionaries associate a key with a value
 - Key is a *unique* identifier
 - Value is something we associate with that key
- Examples in the real world:
 - Phonebook
 - Keys: names
 - Values: phone numbers
 - Dictionary
 - Keys: words
 - Values: word definitions
 - US Government
 - Keys: Social Security number
 - Values: Information about an individual's employment in US

Dictionaries in Python

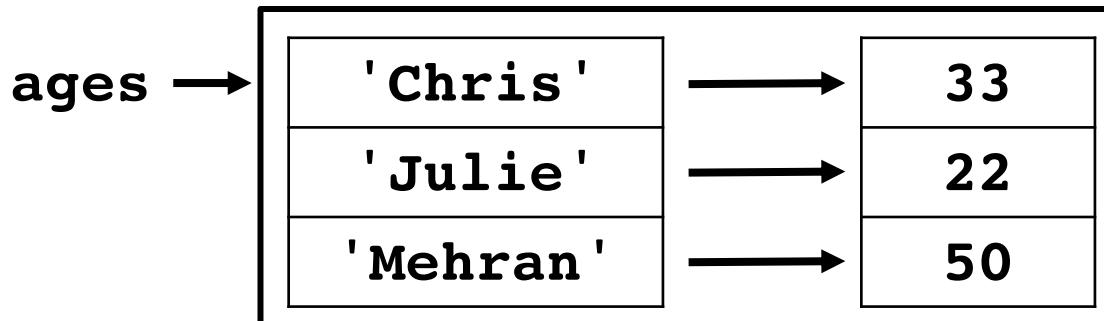

- Creating dictionaries
 - Dictionary start/end with braces
 - Key:Value pairs separated by colon
 - Each pair is separated by a comma

```
ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

```
squares = {2: 4, 3: 9, 4: 16, 5: 25}
```

```
phone = {'Pat': '555-1212', 'Jenny': '867-5309'}
```

```
empty_dict = {}
```

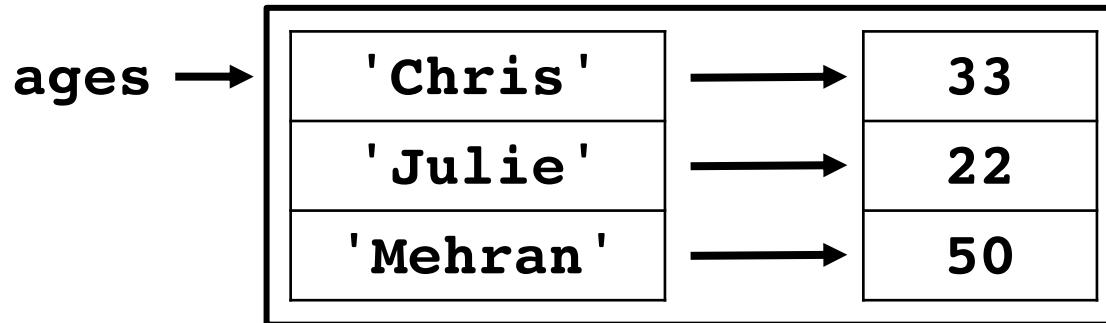

Accessing Elements of Dictionary

- Consider the following dictionary:

```
ages = { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Like a set of variables that are indexed by keys

- Use key to access associated value:

`ages['Chris']` is 33

`ages['Mehran']` is 50

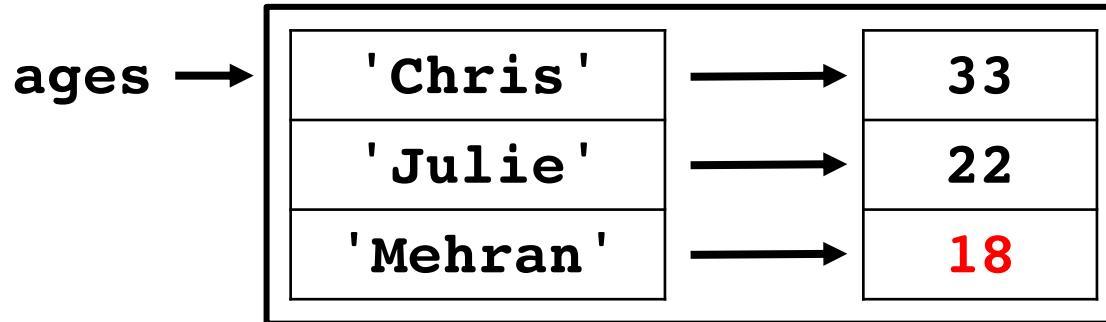

Accessing Elements of Dictionary

- Consider the following dictionary:

```
ages = { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Like a set of variables that are indexed by keys

- Use key to access associated value:

```
ages[ 'Chris' ] is 33
```

```
ages[ 'Mehran' ] is 50
```

- Can set values like regular variable:

```
ages[ 'Mehran' ] = 18
```

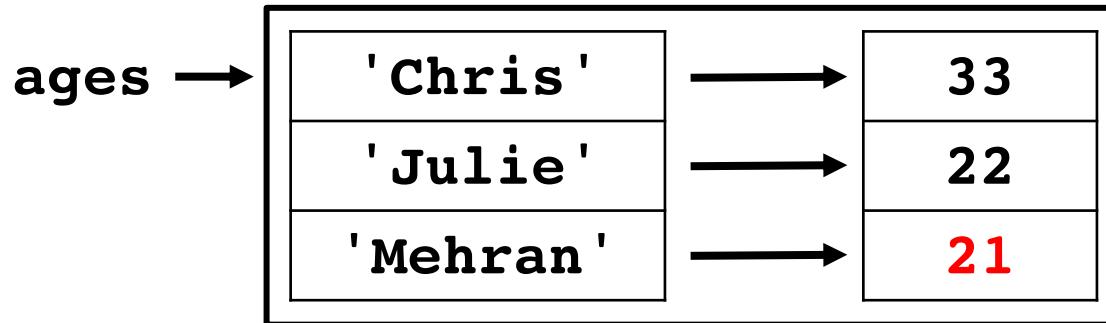

Accessing Elements of Dictionary

- Consider the following dictionary:

```
ages = { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Like a set of variables that are indexed by keys

- Use key to access associated value:

```
ages[ 'Chris' ] is 33
```

```
ages[ 'Mehran' ] is 50
```

- Can set values like regular variable:

```
ages[ 'Mehran' ] = 18
```

```
ages[ 'Mehran' ] += 3
```

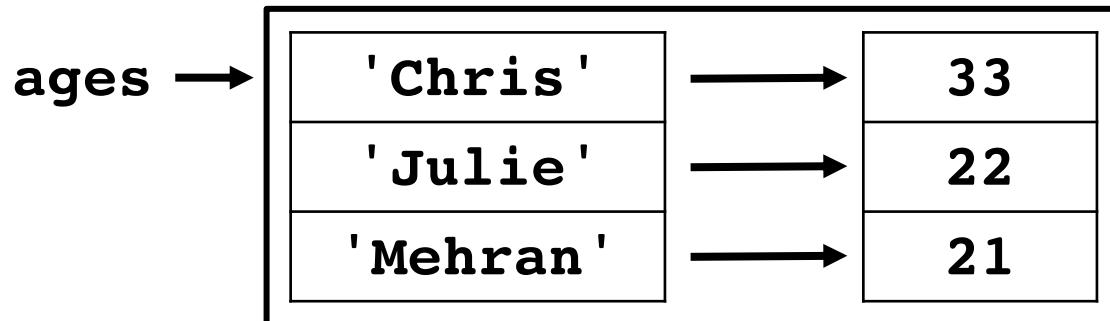

Accessing Elements of Dictionary

- Consider the following dictionary:

```
ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Like a set of variables that are indexed by keys

- Good and bad times with accessing pairs:

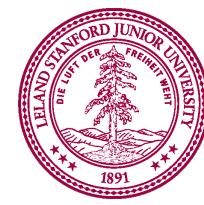

```
>>> julies_age = ages['Julie']
```

```
>>> julies_age
```

```
22
```

```
>>> santas_age = ages['Santa Claus']
```

```
KeyError: 'Santa Claus'
```

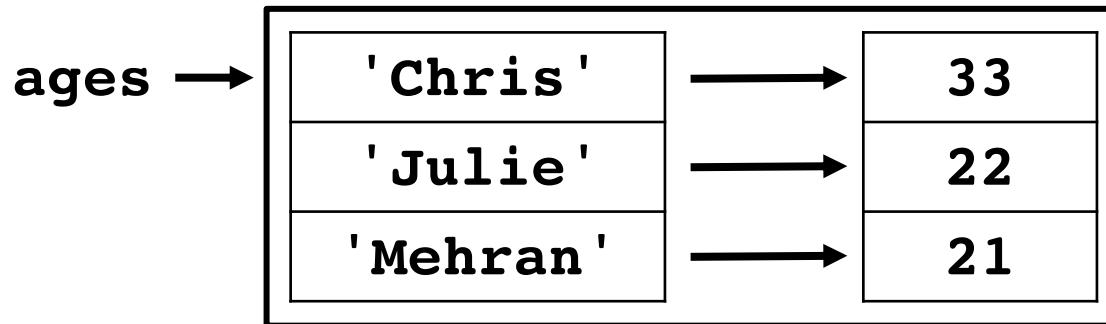

Accessing Elements of Dictionary

- Consider the following dictionary:

```
ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Like a set of variables that are indexed by keys

- Checking membership

```
>>> 'Julie' in ages
```

```
True
```

```
>>> 'Santa Claus' not in ages
```

```
True
```

Adding Elements to Dictionary

- Can add pairs to a dictionary:

```
phone = {}
```

phone → *Empty dictionary*

Adding Elements to Dictionary

- Can add pairs to a dictionary:

```
phone = {}
```

```
phone →
```

' Pat '

' 555-1212 '

```
phone[ 'Pat' ] = '555-1212'
```

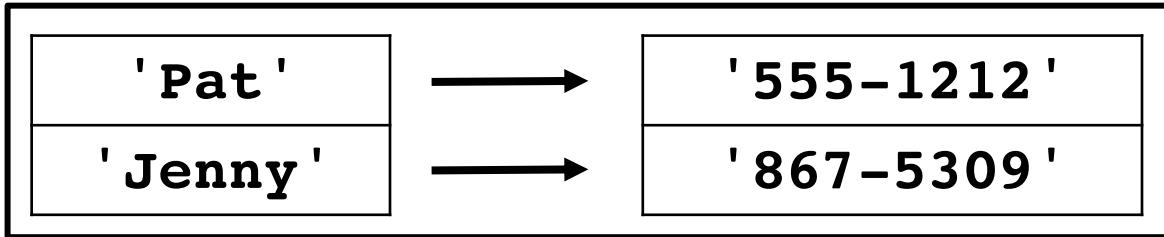

Adding Elements to Dictionary

- Can add pairs to a dictionary:

```
phone = {}
```

```
phone →
```

```
phone[ 'Pat' ] = '555-1212'
```

```
phone[ 'Jenny' ] = '867-5309'
```

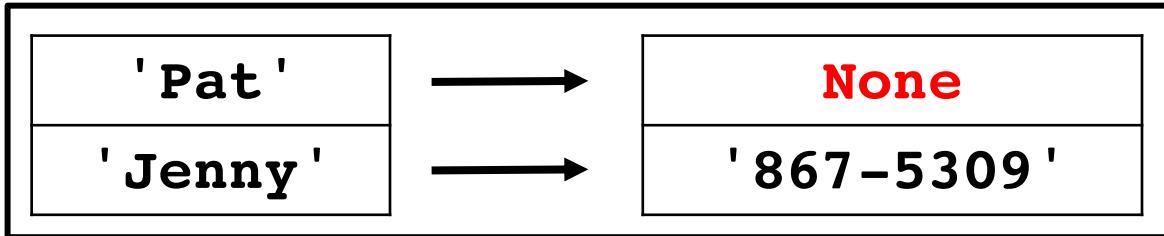

Adding Elements to Dictionary

- Can add pairs to a dictionary:

```
phone = {}
```

```
phone →
```

```
phone[ 'Pat' ] = '555-1212'
```

```
phone[ 'Jenny' ] = '867-5309'
```

```
phone[ 'Pat' ] = None
```

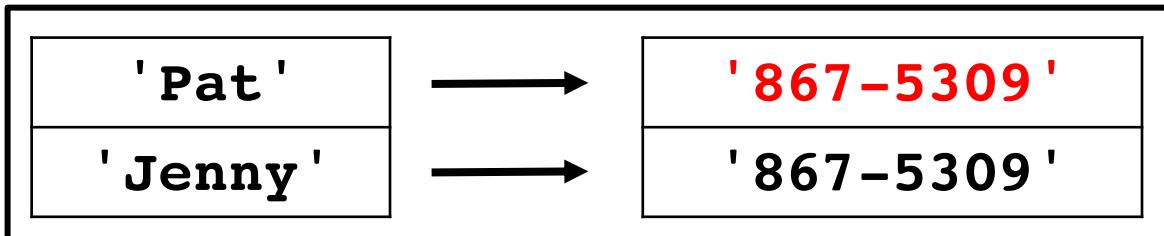

Adding Elements to Dictionary

- Can add pairs to a dictionary:

```
phone = {}
```

```
phone →
```

```
phone[ 'Pat' ] = '555-1212'
```

```
phone[ 'Jenny' ] = '867-5309'
```

```
phone[ 'Pat' ] = None
```

```
phone[ 'Pat' ] = '867-5309'
```

A Word About Keys/Values

- Keys must be immutable types
 - E.g., int, float, string
 - Keys cannot be changed in place
 - If you want to change a key, need to remove key/value pair from dictionary and then add key/value pair with new key.
- Values can be mutable or immutable types
 - E.g., int, float, string, lists, dictionaries
 - Values can be changed in place
- Dictionaries are mutable
 - Changes made to a dictionary in a function persist after the function is done.

Changing Dictionary in a Function

```
def have_birthday(dict, name):
    print("You're one year older, " + name + "!")
    dict[name] += 1

def main():
    ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
    print(ages)
    have_birthday(ages, 'Chris')
    print(ages)
    have_birthday(ages, 'Mehran')
    print(ages)
```

Terminal:

```
{'Chris': 33, 'Julie': 22, 'Mehran': 50}
You're one year older, Chris!
{'Chris': 34, 'Julie': 22, 'Mehran': 50}
You're one year older, Mehran!
{'Chris': 34, 'Julie': 22, 'Mehran': 51}
```

Dictiona-palooza! (Part 1)

```
ages = { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Function: dict.get(key)

- Returns value associated with key in dictionary. Returns **None** if key doesn't exist.

```
>>> print(ages.get('Chris'))
```

```
33
```

```
>>> print(ages.get('Santa Claus'))
```

```
None
```

- Function: dict.get(key, default)

- Returns value associated with key in dictionary. Returns default if key doesn't exist.

```
>>> print(ages.get('Chris', 100))
```

```
33
```

```
>>> print(ages.get('Santa Claus', 100))
```

```
100
```

Dictiona-palooza! (Part 2)

```
ages = { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Function: dict.keys()

- Returns something similar to a range of the keys in dictionary
- Can use that to loop over all keys in a dictionary:

```
for key in ages.keys():
    print(str(key) + " -> " + str(ages[key]))
```

Terminal:

```
Chris -> 33
Julie -> 22
Mehran -> 50
```

- Can turn **keys()** into a list, using the **list** function

```
>>> list(ages.keys())
['Chris', 'Julie', 'Mehran']
```

Dictiona-palooza! (Part 3)

```
ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Can also loop over a dictionary using for-each loop just using name of dictionary:

```
for key in ages:  
    print(str(key) + " -> " + str(ages[key]))
```

Terminal:

```
Chris -> 33  
Julie -> 22  
Mehran -> 50
```

Dictiona-palooza! (Part 4)

```
ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Function: dict.values()

- Returns something similar to a range of the values in dictionary
- Can use that to loop over all keys in a dictionary:

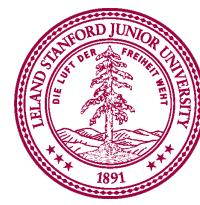

```
for value in ages.values():  
    print(value)
```

Terminal:

```
33  
22  
50
```

- Can turn **values()** into a list, using the **list** function

```
>>> list(ages.values())  
[33, 22, 50]
```

Dictiona-palooza! (Part 5)

```
ages = { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Function: `dict.pop(key)`

- Removes key/value pair with the given key. Returns value from that key/value pair.

```
>>> ages
>>> { 'Chris': 33, 'Julie': 22, 'Mehran': 50}
>>> ages.pop('Mehran')
50
>>> ages
{'Chris': 33, 'Julie': 22}
```

- Function: `dict.clear()`

- Removes all key/value pairs in the dictionary.

```
>>> ages.clear()
>>> ages
{}
```

Functions You Can Apply

```
ages = {'Chris': 33, 'Julie': 22, 'Mehran': 50}
```

- Function: `len(dict)`
 - Returns number of key/value pairs in the dictionary
- Function: `del dict[key]`
 - Removes key/value pairs in the dictionary.
 - Similar to `pop`, but doesn't return anything.

```
>>> ages
{'Chris': 33, 'Julie': 22, 'Mehran': 50}
>>> del ages['Mehran']
>>> ages
{'Chris': 33, 'Julie': 22}
```

Putting it all together:
`count_characters.py`

Bonus fun:
phonebook.py

Learning Goals

1. Learning about dictionaries
2. Building programs using dictionaries

```
{ 'breakfast' : ,  
  'lunch' : ,  
  'dinner' : }
```
